

Box Compression Tester with Screen

Product Info:

A box compression tester is a testing device that is used to measure the compressive strength and stacking performance of packaged products, such as boxes, cartons, and other types of containers. It is commonly used in the packaging industry to ensure that the products being shipped can withstand the rigors of handling, transportation, and storage without damage.

The box compression tester works by applying a compressive load to the packaged product and measuring the force required to compress the product to a certain percentage of its original size. This allows the tester to determine the products & compressive strength and stacking performance, as well as its ability to withstand external forces such as those encountered during handling and transportation.

Box compression testers are used in a variety of industries, including food and beverage, pharmaceuticals, cosmetics, and consumer goods, to ensure that the packaging of products meets the required standards for strength and durability. They are also used by logistics and supply chain companies to test the performance of shipping containers and other packaging materials to ensure that they are suitable for use in their operations.
